TECHNICAL REPORT

ASWEPS REPORT NO. 3

TONGUE OF THE OCEAN RESEARCH EXPERIMENT

A. WAYNE MAGNITZKY

1960

U. S. NAVY HYDROGRAPHIC OFFICE
WASHINGTON, D. C.

ABSTRACT

A research experiment, conducted aboard the USS SAN PABLO for the purpose of studying temperature structure in the waters of the Tongue of the Ocean from 4 to 20 March 1960, is described. The data have been tabulated and listed as Appendixes to the report. Analysis of the data has not been completed; however, a preliminary examination shows that internal waves play a large part in the fluctuation of thermal structure in this area.

FOREWORD

In 1958, the Hydrographic Office was assigned the responsibility for the development of an Antisubmarine Warfare Environmental Prediction System (ASWEPS). This system is a five-year program designed to provide the Fleet with continuing environmental information and predictions in support of antisubmarine warfare operations.

Of paramount importance in the prosecution of this program is the availability of an oceanographic research vessel instrumented especially for ASWEPS requirements. This report deals with a research experiment conducted aboard the USS SAN PABLO (AGS-30) in the Tongue of the Ocean from 4 March to 20 March 1960. It is narrative in nature, containing a tabulation of the data, as well as generalizations resulting from a cursory examination of the data.

It is believed that analysis of the data obtained from this experiment will contribute significantly toward the development of a prediction technique for the thermal structure of the ocean.

E. C. STEPHAN

SCIENTIFIC PERSONNEL

The following civilian scientists participated in the ASWEPS field research program in the Tongue of the Ocean:

Wayne Magnitzky----------Chief Scientist
Robert Farland----------Electronic Engineer
Howard French----------Oceanographer
William Gladfelter----------Oceanographer
Edward Johnson----------Oceanographer
Griffith Knoop----------Oceanographer
Edward Lessmann----------Physical Science Technician
Gordon MacDowell----------Oceanographer
Paul Mazeika----------Oceanographer
Robert Pickett----------Oceanographer
Kemper Reece----------Electronic Development Technician
Douglas Smith----------Oceanographer
Frank Taylor----------Electronic Development Technician

I. INTRODUCTION

A research experiment was designed and implemented to study the interaction of the ocean and atmosphere and to relate these effects to the problems involved in the ASWEPS program. An oceanographic research team, consisting of nine Oceanographers, one Physical Science Technician, one Electronic Engineer, and two Electronic Development Technicians, was assigned to the USS SAN PABLO (AGS-30) to conduct the field work. The Tongue of the Ocean (TOTO) was selected as the most appropriate site for the experiment because it is a unique feature in the ocean with its rather steep slope and extremely flat and deep bottom and because of the availability of a 3-point mooring system installed at 24°35'N, 77°34'W. In addition, environmental results obtained aboard the USNS GIBBS during a preliminary survey of the TOTO in December 1959 and the work of the Woods Hole Oceanographic Institute and the University of Miami indicated that the TOTO would serve as an excellent field laboratory for the study of internal waves. Eighteen oceanographic stations were occupied, including a 5-day anchor station at the 3-point mooring system southeast of High Cay and a 2-day anchor station just east of Big Wood Cay. Figure 1 shows the approximate locations of the stations occupied in the TOTO.

II. RESEARCH EXPERIMENT

The experiment was conducted to determine the distribution in time and space of the horizontal and vertical temperature field; the energy exchange between the sea and the atmosphere was studied, particularly with respect to changes in the vertical temperature structure; data were obtained for use to evaluate the advective term in the distribution equation; studies of the density structure were accomplished by means of temperature and salinity measurements; and associated meteorological data were obtained to supplement the above. Since density is a governing factor in the behavior of internal waves, oceanographic casts were made to measure this variable. From the system of anchored buoys (thermal array) recording concurrently, it is believed that wave length and speed of propagation of the internal waves can be derived. Appendix I outlines a plan and proposed method of analysis for the study of internal waves. Time series data produced by the thermal array will be subjected to power spectrum analysis and the results will be used as a basis for the development of a prediction technique for thermal structure.

A. THERMAL ARRAY

Temperature measuring devices were assembled in an array. This was accomplished by using the anchoring cables of the permanent mooring bridle system, to which were attached 19 wire resistance thermometers at selected depths; an 11-point thermistor chain streamed from the USS SAN PABLO, and by lowering BT's. A schematic diagram of this installation is shown in Figure 2. Results of previous surveys in the TOTO indicated the depth of the thermocline at approximately 400 feet. Accordingly, the electrical cable and sensing elements were fabricated for this depth.

Because the layer depth extended to 650-700 feet during this period, all probe depths were modified aboard ship to cope with this unexpected phenomenon.

The array was designed in the form of three triangles with the apex of each at buoy A. The large triangle was formed by buoys A, B, and C, the length of the sides being 1500 feet. The medium triangle was formed by buoy A and two dan buoys D and E hung from polypropylene rope, 150 feet from the apex A. The small triangle was formed by buoy A and two dan buoys F and G hung from polypropylene rope, 50 feet from the apex A. Spongex floats were used to give the electrical cable the necessary buoyancy. The data from the resistance thermometers were printed out on chart paper by two Brown recorders, twenty seconds being required to scan all nineteen probes. Figure 3 shows part of the array streamed from the USS SAN PABLO to one of the mooring buoys and Figure 4 shows a close-up of one of the mooring buoys.

Another component of the thermal array consisted of a thermistor chain streamed from the USS SAN PABLO. This equipment was fabricated at the Hydrographic Office,using 14-conductor Vector cable and eleven thermistor probes plus a pressure element. The chain was constructed so that the pressure element and the last thermistor probe could be lowered to at least 1200 feet. Each probe consisted of a previously calibrated bridge circuit and provided a precise voltage to a DYMAC voltage - to - frequency connector, which in turn was counted and then digitally presented on paper tape at the rate of twelve data points every 65 seconds. Five of the thermistor probes malfunctioned so that data were collected at depths of 580, 650, 670, 690, 730, 750 and 770 feet, respectively.

Mechanical 900-foot BT's and paired reversing thermometers on the Nansen bottles were used to supplement the temperature data from the thermal array.

B. OTHER PARAMETERS

In order to arrive at a satisfactory technique to obtain solar irradiation measurements at sea, the SAN PABLO was instrumented with pyrheliometers, incident sensing from the stem and deckhouse, and reflected sensing from the stem and port/starboard booms. Flat-plate radiometers were also utilized at the stem location to record long-wave incoming/reflected values. For this investigation, Daystrom-Weston Corporation recording instruments, with specially furnished ranges, were installed. The instruments were found to perform well within field requirements and with the flexibility of ranges available, many erratic patterns previously doubtful are now believed to be fully documented. Figure 5 shows the radiation instrument action used.

The Roberts Current Meter was used to obtain profiles of water movement. The meters presented no problems and a good set of current

I. INTRODUCTION

A research experiment was designed and implemented to study the interaction of the ocean and atmosphere and to relate these effects to the problems involved in the ASWEPS program. An oceanographic research team, consisting of nine Oceanographers, one Physical Science Technician, one Electronic Engineer, and two Electronic Development Technicians, was assigned to the USS SAN PABLO (AGS-30) to conduct the field work. The Tongue of the Ocean (TOTO) was selected as the most appropriate site for the experiment because it is a unique feature in the ocean with its rather steep slope and extremely flat and deep bottom and because of the availability of a 3-point mooring system installed at 24°35'N, 77°34'W. In addition, environmental results obtained aboard the USNS GIBBS during a preliminary survey of the TOTO in December 1959 and the work of the Woods Hole Oceanographic Institute and the University of Miami indicated that the TOTO would serve as an excellent field laboratory for the study of internal waves. Eighteen oceanographic stations were occupied, including a 5-day anchor station at the 3-point mooring system southeast of High Cay and a 2-day anchor station just east of Big Wood Cay. Figure 1 shows the approximate locations of the stations occupied in the TOTO.

II. RESEARCH EXPERIMENT

The experiment was conducted to determine the distribution in time and space of the horizontal and vertical temperature field; the energy exchange between the sea and the atmosphere was studied, particularly with respect to changes in the vertical temperature structure; data were obtained for use to evaluate the advective term in the distribution equation; studies of the density structure were accomplished by means of temperature and salinity measurements; and associated meteorological data were obtained to supplement the above. Since density is a governing factor in the behavior of internal waves, oceanographic casts were made to measure this variable. From the system of anchored buoys (thermal array) recording concurrently, it is believed that wave length and speed of propagation of the internal waves can be derived. Appendix I outlines a plan and proposed method of analysis for the study of internal waves. Time series data produced by the thermal array will be subjected to power spectrum analysis and the results will be used as a basis for the development of a prediction technique for thermal structure.

A. THERMAL ARRAY

Temperature measuring devices were assembled in an array. This was accomplished by using the anchoring cables of the permanent mooring bridle system, to which were attached 19 wire resistance thermometers at selected depths; an 11-point thermistor chain streamed from the USS SAN PABLO, and by lowering BT's. A schematic diagram of this installation is shown in Figure 2. Results of previous surveys in the TOTO indicated the depth of the thermocline at approximately 400 feet. Accordingly, the electrical cable and sensing elements were fabricated for this depth.

Because the layer depth extended to 650-700 feet during this period, all probe depths were modified aboard ship to cope with this unexpected phenomenon.

The array was designed in the form of three triangles with the apex of each at buoy A. The large triangle was formed by buoys A, B, and C, the length of the sides being 1500 feet. The medium triangle was formed by buoy A and two dan buoys D and E hung from polypropylene rope, 150 feet from the apex A. The small triangle was formed by buoy A and two dan buoys F and G hung from polypropylene rope, 50 feet from the apex A. Spongex floats were used to give the electrical cable the necessary buoyancy. The data from the resistance thermometers were printed out on chart paper by two Brown recorders, twenty seconds being required to scan all nineteen probes. Figure 3 shows part of the array streamed from the USS SAN PABLO to one of the mooring buoys and Figure 4 shows a close-up of one of the mooring buoys.

Another component of the thermal array consisted of a thermistor chain streamed from the USS SAN PABLO. This equipment was fabricated at the Hydrographic Office,using 14-conductor Vector cable and eleven thermistor probes plus a pressure element. The chain was constructed so that the pressure element and the last thermistor probe could be lowered to at least 1200 feet. Each probe consisted of a previously calibrated bridge circuit and provided a precise voltage to a DYMAC voltage - to - frequency connector, which in turn was counted and then digitally presented on paper tape at the rate of twelve data points every 65 seconds. Five of the thermistor probes malfunctioned so that data were collected at depths of 580, 650, 670, 690, 730, 750 and 770 feet, respectively.

Mechanical 900-foot BT's and paired reversing thermometers on the Nansen bottles were used to supplement the temperature data from the thermal array.

B. OTHER PARAMETERS

In order to arrive at a satisfactory technique to obtain solar irradiation measurements at sea, the SAN PABLO was instrumented with pyrheliometers, incident sensing from the stem and deckhouse, and reflected sensing from the stem and port/starboard booms. Flat-plate radiometers were also utilized at the stem location to record long-wave incoming/reflected values. For this investigation, Daystrom-Weston Corporation recording instruments, with specially furnished ranges, were installed. The instruments were found to perform well within field requirements and with the flexibility of ranges available, many erratic patterns previously doubtful are now believed to be fully documented. Figure 5 shows the radiation instrument action used.

The Roberts Current Meter was used to obtain profiles of water movement. The meters presented no problems and a good set of current

data was obtained while on anchor station.

Wave data were obtained using the "Splashnik", developed by the David Taylor Model Basin, as the basic sensing element. The system consists of a buoy assembly containing a transducer and transmitter, a wide band FM receiver, an electronic low pass filter, and a recorder. The transmitter emits a signal that varies in frequency proportional to the acceleration imparted to the buoy assembly by wave action. This signal is received by the antenna mounted on the ship and is fed into a receiver. In the receiver, the frequency changes are converted to a varying dc voltage which is proportional to the acceleration. The dc voltage is placed on the input of an adjustable low pass filter which cuts off the signals produced by the surface chop of the sea, but passes unaltered the lower frequency signals produced by the larger and longer waves. The output of the filter unit is then recorded on magnetic tape. Figure 6 shows the float assembly, or "Splashnik", of the wave height telemetering buoy system.

Oceanographic casts, using the Nansen bottle and paired reversing thermometers, were made for obtaining water samples in order to compute density.

Meteorological data were obtained using standard equipment, as well as time-lapse photographs of cloud cover. Wind measurements were made at three levels.

III. INSTRUMENTATION TEST AND EVALUATION

A. ELECTRIC CABLE REELS

Installed aboard the survey vessel were two models of newly-manufactured electric cable reels of 12,000 and 2,000 foot capacity, respectively. Figure 7 shows the smaller cable reel and winch. These units, designed to operate with electrically conductive cable (six conductors), offer infinite speed control in both powered lowering and hoisting positions and have the advantageous feature of rapid interchangeability of the reels. Approximately 30 lowerings were made with the smaller unit, utilizing two models of electronic bathythermographs. Operation was found to be smooth and trouble free. In addition, since there was no universal connector for both BT's, drums were changed daily. This operation was performed in about 10 minutes with insignificant delays in data acquisition.

B. ELECTRONIC BATHYTHERMOGRAPHS

Two models of an electronic bathythermograph, the WHOI Subaqueous Temperature Probe and the HYDRO Linear Thermistor System were tested during this period with excellent results. Briefly, both consist of a dc pick-off and self balancing resistance bridge circuit with a thermistor sensor as the variable leg. This was the first deepwater test of these instruments, both of which have a 600 psi (1350 foot) depth limitation.

Figures 8 and 9 show a comparison of the traces obtained by the electronic BT's with the corresponding standard Nansen cast and 900 foot mechanical BT. A statistical analysis of the electronic BT data collected on this cruise will be made as compared to other methods of temperature-depth measurements. Data collected from future tests will likewise be analyzed, and from these results a final design will be selected. Figure 10 shows the WHOI electronic BT and Figure 11 shows the HYDRO linear electronic BT.

IV. OCEANOGRAPHIC AND METEOROLOGICAL OBSERVATIONS

This section is a resume of the kind and quantity of data obtained. These data are tabulated in the Appendixes as indicated below.

A. TEMPERATURE DATA

The following methods were used to obtain temperature with depth data. In general, when two or more instruments were used simultaneously, the data agreed well.

1. Mechanical 900' BT's - 801 BT's were obtained to an average depth of 840 feet. The data, 24360 data points, are presented in Appendix II.

2. Hydro electronic linear BT - 14 traces down and 14 traces up were plotted by the X-Y recorder.

3. WHOI electronic BT - 19 traces down and 19 traces up were plotted by the X-Y recorder.

4. Thermistor Chain - Approximately 24 hours, or 15,440 data points, of continuous data were recorded. The data have not been completely reduced at this time.

5. Reversing thermometer - 645 data points were obtained and are presented in Appendix III.

6. Thermal array - Approximately 26 hours of continuous data were recorded on two 12-point Brown recorders. However, only 17 hours of the data are considered useful and the data taken at the 700' depth are presented in Appendix IV. Data from all sensors total 61,200 data points.

B. SEA AND SWELL

Visual observations were made every 15 minutes. Approximately 1/2 hour of Splashnik data was recorded on magnetic tape.

C. CURRENTS

Eighty-seven current profiles at seven depths were obtained, representing 616 data points. The data are presented in Appendix V.

D. OCEANOGRAPHIC CASTS

Forty-three Nansen casts were made, including five deep casts and representing 645 data points each of temperature, salinity, and computed sigma - t and sound velocity. The data are presented in Appendix III.

E. METEOROLOGICAL DATA

These data were obtained with standard meteorological instrumentation.

1. Air temperatures - 216 hours of wet and dry bulb data were obtained.

2. Winds - Wind speed and direction were measured at the mast and bow. The bow-height sensor measured wind speed on a continuous basis.

3. Radiation - Continuous recordings were made using five pyrheliometers and one flat-plate radiometer. 28,800 data points were obtained with the pyrheliometers and are presented in Appendix VI.

V. SHIPBOARD DATA REDUCTION

Data reduction and processing were successfully completed aboard a Navy oceanographic vessel for the first time. Six hour watches were maintained continuously in the data center established aboard the USS SAN PABLO. Meteorological data, mechanical BT's, ocean casts, and thermistor chain data were encoded and key punched onto IBM cards. The data were checked and verified aboard ship and publication listings obtained upon return to HYDRO.

VI. PRELIMINARY EXAMINATION OF OCEANOGRAPHIC DATA

The Tongue of the Ocean is widely recognized for its unique features, particularly with respect to size, shape,and depth. To what extent the geometry of the Basin completely influences the physical properties is not known. However, the distribution of these physical properties is apparently influenced by changing climatic conditions, prevailing meteorological situations, and the oceanographic circulation patterns east of the Bahamas. Local changes, particularly internal water movements, appeared to be related directly to the configuration of the ocean basin.

A. CURRENTS

To determine the circulation pattern in the Tongue of the Ocean, density currents were computed relative to the 300-meter level. Comparison of these currents with actual hourly observations taken during the period 9 to 13 March at the moor show excellent agreement. Analyses of dynamic current data indicate a circulation pattern in which water

courses southward through the eastern portion, gradually curves westerly, and then sets northward through the western portion. Further analyses of these data suggest the possibility of two major eddies, one located between the northern and central transect and the other located between the central and southern transect.

Previous investigations have shown the currents in this area to be weak and subject to influence by prevailing winds. A review of the currents while in the mooring bridle substantiates this latter fact, but also shows current speeds as great as 1 knot. The most striking example of wind-driven currents can be seen when comparing data for 11 and 12 March. During this period, water movement in the upper layer changed almost 180° under the influence of strong northerly winds; maximum speeds were obtained coincident with maximum winds. The following statements are relevant to the 87 observations made during the period 9 to 13 March:

1. Current gradient 10 to 100 meters:
   Average, 0.2 knot; range, 0.0 to 0.8 knot

2. Current speed at 10 meters:
   Average, 0.5 knot; range, 0.0 to 1.0 knot

3. Prevailing current direction 10 to 100 meters : northeasterly

4. Current direction variation 10 to 100 meters :
   Average, 40°; range, 0° to 160° (Difference decreases the longer a wind persists from one direction)

5. The strongest current (1.0 knot) was observed setting southeast during a northeasterly wind whose speed increased from 16 to 24 knots in 4 hours.

6. Below 100 meters, the current speed averaged about 0.3 knot with a range from <0.2 to 0.5 knot the first day on station. The direction varied from northerly to east-northeasterly. The remainder of the time the current speed averaged about 0.5 knot with a range from <0.2 to 0.7 knot. The direction varied from north-northeasterly to southeasterly.

B. TEMPERATURE

1. Surface

The oceanographic observations collected during the Tongue of the Ocean survey clearly demonstrate the homogeneity of the water masses. Sea surface temperatures varied from a minimum of 23.76° to a maximum of 24.10°C, or a difference of 0.34°C (0.61°F). From Tinker Rocks to Green Cay, temperatures showed an increase from 23.76°C to 23.99°C, the latter temperature being measured in the vicinity of Green Cay. Similarly,

the distribution of sea surface temperature over the northern portion, from near Mastic Point to Goulding Cay, showed a corresponding increase in temperature, with values ranging from 23.84°C in the western sector to 23.94°C in the eastern sector. On the other hand, the variation of temperature along the central transect, extending from station 10 to station 12 showed a decrease in sea surface temperature with values ranging from 24.00°C in the western sector to 23.87°C in the eastern sector. The general trend of sea surface temperature along a longitudinal axis extending from station 1 to station 17 showed that highest temperatures were observed in the northern one-third of the survey area.

2. Vertical Cross Sections

a. The oceanographic stations which were taken on a line extending from Tinker Rocks to Green Cay, stations 3 through 6, show the same general properties at each location (Fig. 12). The vertical distribution of water temperature showed an increase between the surface and intermediate depths with values ranging from 0.16° to 0.24°C between stations 3 and 4. Although less marked, a similar positive temperature gradient existed between stations 5 and 6 with temperature increases ranging from 0.20° to 0.04°C. The depth of maximum temperature was deepest at station 4, 135 meters, and shallowest at station 3, 70 meters. The main thermocline began at a depth of approximately 140 meters at station 3 and sloped downward toward the east to a depth of approximately 150 meters.

b. The transect in the central portion of the survey area, namely stations 10 through 12 (Fig. 13), also shows temperature increases at depth; however, the magnitude of these temperature increases is not as great as in the southern transect. Specifically, at station 10 the surface layer is characterized by a decrease in temperature of approximately .5°C to a depth of 20 meters and then a very slight increase of .2°C to 35 meters. A gradual decrease in temperature was observed from this depth to the main thermocline, which began at approximately 180 meters. On the other hand, the intrusion of warm water can be noted at stations 11 and 12 at depths of approximately 80 and 140 meters at station 1 and at depths of 10 and 100 meters at station 12. The main thermocline along this transect appeared roughly horizontal at the 185-meter level between stations 10 and 11 and then depths generally decreased, the thermocline sloping gradually upward to depths of 150 meters.

c. The transect for the northern portion, stations 15 to 18, Figure 14, demonstrated characteristics similar to those observed in the central and southern portions. At all stations, positive temperature gradients were noted at depth, the strongest of these being found at stations 16 and 17 where temperature increases on the order of .12°C were found. One striking feature not in evidence at the southern transect was a core of colder water at approximately 100 meters between stations 16 and 17. Apparently, this tongue of colder water was trapped by intrusion of warmer water at the 150 meter level. The main thermocline

generally sloped downward from west to east from approximately 135 meters at station 15 to 170 meters at station 18.

3. Longitudinal Cross Section - The longitudinal cross section, extending from south to north (Fig. 15), shows the same general features described in the latitudinal cross sections. The main thermocline slopes downward from south to north, from a mean depth of 150 meters at station 4 to a maximum depth of 190 meters at station 13. The factors producing such a change can be attributed to either piling up of water under wind pressure or tidal influence. The direct cause cannot be determined precisely inasmuch as the survey was conducted in approximately 4 days.

4. Anchor Station Data - Surface temperature of the TOTO water at $24^{o}35'N$, $77^{o}34'W$ ranged from 23.61^{o} to $23.99^{o}C$, or a range of $0.28^{o}C$, during the six days SAN PABLO was tied in the mooring bridle system. During this same period of time, layer depth fluctuated from 525 feet to 695 feet, or a range of 170 feet. Daily fluctuations of layer depth were as follows:

Day March	Layer Depth Feet	Range of Layer Depth Feet
7	580-650	70
8	595-640	45
9	605-685	80
10	650-695	45
11	605-685	80
12	610-655	45
13	530-655	125
14	525-575	50

C. SALINITY

1. Surface - The horizontal distribution of surface salinity shows a gradual increase from the entrance of the Tongue of the Ocean southward. At the southernmost transect, salinity values ranged from $36.60^{o}/00$ on the western side to $36.75^{o}/00$ on the eastern side. At the northernmost transect, values were nearly the same, displaying properties typical of open ocean conditions. The transect extending across the central portion, on the other hand, showed higher salinity values on the western side than on the eastern side. Under normal conditions, higher salinity values would be expected on the eastern side, principally due to shoalness of the water area and its ability to produce high saline water. Salinity values along the central transect varied from $36.70^{o}/00$ to $36.52^{o}/00$.

2. Vertical Cross Sections

a. Stations 3 through 6 - Approximately 4 hours were required to occupy stations 3 through 6; therefore, the data obtained on this

cross section are nearly synoptic in nature. Analysis of all salinity profiles for this period show an intrusion of higher saline water at depths ranging from 140 meters at station 3 to 70 meters at station 6 (Fig. 16). Probably, this intrusion of high saline water originates from the shoal water area surrounding the Tongue. The magnitude of the salinity increase ranges from .39^0/00 at station 3 to .08^0/00 at station 6. A marked halocline exists below the depth of maximum salinity, with gradual decreasing salinity values to depths of 600 meters. For the most part, the halocline slopes generally upward from west to east.

b. Stations 10, 11 and 12 - As in the southern transect, these stations were occupied during a three to four hour period; and hence, are nearly synoptic. Similar properties can be found in this transect as were found in the southern transect. First, the increase in salinity with depth can be found at each station. This salinity increase varies from .26^0/00 at the western station to .40^0/00 at station 11 to .35^0/00 at the easternmost station (Fig. 17). The depth of maximum salinity ranges from 160 meters at station 10 to 180 meters at station 11 to 150 meters at station 12. The halocline that exists below these depths is quite marked, with salinity values decreasing gradually.

c. Stations 15 through 18 - Although the horizontal distribution of sea surface salinity shows little change between stations 14 and 18 (Fig. 18), the vertical distribution shows a radical change at each station. As in the previous transects, the intrusion of high saline water can be found at approximately the same depths. For example, at station 15, the increase in salinity from the surface to 190 meters is .28^0/00. Similar increases can be found at the other stations, with gradients ranging from .31^0/00 at station 16 to .37^0/00 at station 18. The depth of maximum salinity along this transect is nearly horizontal, ranging from 190 meters at station 15 to 185 meters at station 16, 170 at station 17 to 180 at station 18. The salinity decrease below this level is less marked than at the southern transects, and in all observations, salinity values are above 36.00^0/00.

3. Longitudinal Cross Section - Figure 19 has been prepared to show the longitudinal distribution of horizontal and vertical salinity variations in the Tongue of the Ocean. This figure clearly illustrates the general increase in surface salinity values, with highest readings being obtained in the southern portion and lowest values being obtained in the northern portion. It also clearly illustrates the intrusion of high saline water throughout the entire Tongue of the Ocean. Figure 19 illustrates that the depth of maximum salinity slopes downward from a least depth of 100 meters at station 1 to a maximum depth of 180 meters at station 11. Variation in salinity below these depths appears generally constant. On the other hand, the distribution of salinity above this level varied considerably from north to south. The Tongue of the Ocean appears to be divided into two cells, one being typical of the region between station 1 and station 7 and the other being typical of the area between stations 7 and 18. The isohalines between station 7

and 18 slope gradually downward, and the surface values of $36.77^{0}/00$ at station 7 can be found at a depth of 140 meters at station 18.

D. DENSITY

1. Surface - The horizontal distribution of surface density shows highest values in the southern portion of the Tongue. Density values (expressed as sigma - t) increase from 24.78 along the northern transect to 25.09 at the southernmost station. In general, the highest density values are found along the western portion of the basin and minimum density values are found along the eastern portion of the basin. An example of this horizontal change can be found by comparing the values along the midtransect. In this example, density values range from 24.95 at station 10 to 24.85 at station 12. A similar change can be noted at the northern transect, although the magnitude is less marked than over the central portion.

2. Vertical Cross Sections

a. The vertical distribution of density along the southern transect demonstrates that the waters in this region are nearly isopycnal (Fig. 20). At station 3, isopycnal conditions can be found to depths of about 40 meters, whereas, at station 4 they can be found to depths of 20 meters. This condition also exists at station 5. At station 6, unstable conditions, probably arising from the intrusion of high saline water off the shoal banks, creates a density inversion in which density values increase from 24.87 to 25.00. The pycnocline commences at approximately 150 meters at stations 3 through 5 and approximately 170 meters at station 6. For the most part, isopycnals along this transect are nearly horizontal, except between stations 5 and 6 where a horizontal gradient exists causing the isopycnals to slope gradually downward.

b. Stations 10 through 12 - No evidence of density inversions can be found along this transect (Fig. 21). Nearly isopycnal conditions prevail from the surface to depths of approximately 50 meters, with a gradual increase below this depth. The pycnocline begins at depths of approximately 160 meters and the isopycnals are nearly horizontal across the entire transect.

c. Along the northern transect, isopycnal conditions prevail from the surface to 90 meters at station 15, decreasing eastward to approximately 40 meters at station 18 (Fig. 22). As in the central transect, a gradual increase in density can be found between this level and the main pycnocline which can be found at approximately 150 meters at all stations.

3. Longitudinal Cross Section - The longitudinal variation in density is shown in Figure 23. The most striking feature of this figure is the orientation of the main pycnocline, which for the most part is nearly horizontal below depths of 150 meters. Above this level, the density

change is relatively slight, and the circulation structure described under paragraph A, above, is clearly evident.

VII. CONCLUSIONS

A preliminary examination of the data shows that internal waves play a large part in the fluctuation of thermal structure in this area. The data will be carefully analyzed to determine whether the modes of oscillation of the internal waves are simple. If they are, the prediction of thermal structure with reasonable accuracy can be simplified.

A research vessel, instrumented especially for ASWEPS requirements, would allow for the continuation of experiments of this nature.

APPENDIX I

SIMULTANEOUS TEMPERATURE OBSERVATIONS AT MEAN DEPTH OF THERMOCLINE TO STUDY INTERNAL WAVES

APPENDIX I
SIMULTANEOUS TEMPERATURE OBSERVATIONS AT MEAN DEPTH OF THERMOCLINE TO STUDY INTERNAL WAVES

In planning a survey of temperatures to observe the effect of internal wave movement, some assumption about the speed of propagation must be made. Three sources of value are available:

1. E. C. LaFond of USNEL has attributed the movement of surface sea slicks to the passage of internal waves with resulting water convergence at the surface just behind the crest of the internal wave. In shallow water (approximately 50 feet) off the California coast these slicks have been observed to travel at 30 feet per minute.

2. Preliminary inspection of the 3-buoy temperature records made at Texas Tower No. 4 indicates a speed of internal wave propagation of approximately 100 feet per minute.

3. Assuming these waves are gravity waves at the interface between two different homogeneous water layers, speed has been calculated from the formula (Lamb, 1945):

$$c = \sqrt{\frac{(\rho-\rho')\, g/k}{\rho' \coth kh' + \rho \coth kh}}$$

where ρ = density of water in lower layer

ρ' = density of water in upper layer

h = thickness of lower layer

h' = thickness of upper layer

$k = \frac{2\pi}{\lambda}$ where λ = wave length

In TOTO, 29°C and 36.7°/oo were used for the upper layer, ρ' = 1.02336. The mixed layer is said to fluctuate between 175 and 300 feet; h' was taken

as 300 feet and h as 3600 feet. The speed of propagation increases with increasing wave length according to the formula; values range from 9 feet per minute for 4.5-foot waves (the smallest which can just be observed with a 15 sec/cycle time on our recorder) to a maximum of 190 feet per minute for 3000-foot (or greater) waves.

OBSERVATIONAL NETWORK:

As the internal waves, which will be measured, will vary from one lunar day (24.84 hours) to approximately one minute, wave lengths will range from 50 miles to approximately 20 feet. To determine the vector, K (whose direction is the direction of propagation and whose magnitude is "wave number") as great a spacing of observations as possible is desirable. However, this spacing can be no greater than $\frac{\lambda}{2}$ Therefore, 3 different triangular spacings of the temperature sensors used are suggested:

SPACING (FEET)	VELOCITY CALCULATED FROM GRAVITY WAVE EQUATION ft/min	SHORTEST WAVE PERIOD (MINUTES) WHICH WILL BE DETECTED ASSUMING: 30 ft/min	100 ft/min
10	1	3/4	< 1/2
200	5	13	4
1730	25	120	35

The duration of the continuous observation period should be at least a week or more to pick up the tidal cycles.

The depth of the thermal sensors should be at the mean depth of the

thermocline as determined by several BT obs over at least a 2-hour period.

METHOD OF ANALYSIS:

The method will be by Fourier analysis as follows, in addition to single station power spectrum analysis. Four assumptions are made:

1. The three resistance thermometers are located at the same depth near the average mid-depth of the thermocline and are sufficiently restrained from swinging as a pendulum to maintain a fixed position despite horizontal currents.

2. The vertical movement of the thermocline is never great enough to cause the sensors to be in either the mixed surface layer or in the bottom layer of small vertical temperature gradient.

3. The vertical temperature gradient within the thermocline is constant.

4. Progressive internal wave components in the area have infinite crests of constant amplitude but each component moves independently.

Under these assumptions, the temperature measured by each thermometer during an interval of record "T" can be approximated by a Fourier Series plus a constant term:

$$T(x,y,t) = \overline{T} + \sum_{n=1}^{\infty} C_n \cos\left(K_{1n}X + K_{2n}y - \frac{2\pi nt}{T} - \delta_n\right)$$

where: $K_{1n}^2 + K_{2n}^2 = K_n^2 = \left(\frac{2\pi}{\lambda_n}\right)^2$ = square of wave number of n^{th} component

λ_n = wave length of n^{th} component

$K_{1n} = K_n \cos\theta_n$

$K_{2n} = K_n \sin\theta_n$

θ_n = direction of normal to n^{th} infinite crested wave component

$C_n^2 = a_n^2 + b_n^2$ = square of amplitude of n^{th} component

$\delta_n = \tan^{-1} b_n/a_n$ = phase of n^{th} component

Expanding twice:

$$T(x,y,t)=\overline{T}+\sum_{n=1}^{\infty} C_n \cos(K_{1n}X+K_{2n}y)\cos\left(\frac{2\pi nt}{T}+\delta_n\right)+C_n \sin(K_{1n}X+K_{2n}y)\sin\left(\frac{2\pi nt}{T}+\delta_n\right)$$

$$=\overline{T}+\sum_{n=1}^{\infty}\cos(K_{1n}X+K_{2n}y)\,C_n\left[\cos\frac{2\pi nt}{T}\cos\delta_n-\sin\frac{2\pi nt}{T}\sin\delta_n\right]+\sin(K_{1n}X+K_{2n}y)\,C_n$$

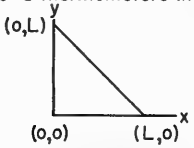
$$\left[\sin\frac{2\pi nt}{T}\cos\delta_n+\cos\frac{2\pi nt}{T}\sin\delta_n\right]$$

Substituting $a_n=C_n\cos\delta_n \quad b_n=C_n\sin\delta_n$

$$T(x,y,t)=\overline{T}+\sum_{n=1}^{\infty}\cos(K_{1n}X+K_{2n}y)\left[a_n\cos\frac{2\pi nt}{T}-b_n\sin\frac{2\pi nt}{T}\right]+\sin(K_{1n}X+K_{2n}y)$$

$$\left[a_n\sin\frac{2\pi nt}{T}+b_n\cos\frac{2\pi nt}{T}\right]$$

Example: 3 thermometers in right triangle



Let $L=\frac{1}{2}$ shortest wave length to be measured

$$T(o,o,t)=\underset{\text{OF TEMPERATURE}}{\overset{\text{TIME SERIES}}{\text{AT ORIGIN}}}=\overline{T}+\sum_{n=1}^{\infty}a_n\cos\frac{2\pi nt}{T}-b_n\sin\frac{2\pi nt}{T}$$

Solving for a specific value a_ℓ of a_n by multiplying both sides by $\cos\frac{2\pi\ell t}{T}\,dt$ and integrating from t=o to t=T the term with $\overline{T}$ is zero at both limits of integration since ℓ is a specific integer, the integrand from the right hand portion of the summation becomes $-b_n\sin\frac{2\pi nt}{T}\cos\frac{2\pi\ell t}{T}$ which can also be expressed as $-\frac{b_n}{2}\sin\frac{2\pi nt+2\pi\ell t}{T}-\frac{b_n}{2}\sin\frac{2\pi nt-2\pi\ell t}{T}$ which when integrated with limits of t=o and t=T becomes zero for every value of n, and the integrand of the left hand term in the summation gives the only contribution and at that only for $n=\ell$:

$$\int_o^T T(o,o,t)\cos\frac{2\pi\ell t}{T}\,dt=\sum_{n=1}^{\infty}\int_o^T a_n\cos\frac{2\pi nt}{T}\cos\frac{2\pi\ell t}{T}\,dt$$

$$=\sum_{n=1}^{\infty}\int_o^T\frac{a_n}{2}\left[\cos\frac{2\pi}{T}(n+\ell)t+\cos\frac{2\pi}{T}(n-\ell)t\right]dt$$

All integrals of this summation are zero except for $n=\ell$:

$$=\frac{a_\ell}{2}\int_o^T\left[\cos\frac{4\pi\ell t}{T}+\cos 0\right]dt=\frac{a_\ell}{2}\,T$$

$$a_\ell=\frac{2}{T}\int_o^T T(o,o,t)\cos\frac{2\pi\ell t}{T}\,dt$$

Similiarly solving for b_ℓ by multiplying both sides by $\sin\frac{2\pi\ell t}{T}\,dt$ and integrating from t=o to t=T:

$$b_\ell=-\frac{2}{T}\int_o^T T(o,o,t)\sin\frac{2\pi\ell t}{T}\,dt$$

Use $T(L,o,t) = \underset{\text{AT POINT } (L,o)}{\overset{\text{TIME SERIES}}{\text{OF TEMPERATURES}}} = \overline{T} + \sum_{n=1}^{\infty} \left[a_n \cos K_{1n} L + b_n \sin K_{1n} L\right] \cos \frac{2\pi nt}{T} + \left[a_n \sin K_{1n} L - b_n \cos K_{1n} L\right] \sin \frac{2\pi nt}{T}$

Solving for Fourier coefficients for a specific value ℓ of n in a similiar manner to preceding:

$$a_\ell \cos K_{1\ell} L + b_\ell \sin K_{1\ell} L = \frac{2}{T} \int_0^T T(L,o,t) \cos \frac{2\pi \ell t}{T} \, dt$$

$$a_\ell \sin K_{1\ell} L - b_\ell \cos K_{1\ell} L = \frac{2}{T} \int_0^T T(L,o,t) \sin \frac{2\pi \ell t}{T} \, dt$$

Knowing a_ℓ and b_ℓ solve these simultaneous equations for $\sin K_{1\ell}$ and $\cos K_{1\ell}$ and thereby evaluate $K_{1\ell}$

Use $T(o,L,t) = \underset{\text{AT POINT } (O,L)}{\overset{\text{TIME SERIES}}{\text{OF TEMPERATURES}}} = \overline{T} + \sum_{n=1}^{\infty} \left[a_n \cos K_{2n} L + b_n \sin K_{2n} L\right] \cos \frac{2\pi nt}{T} + \left[a_n \sin K_{2n} L - b_n \cos K_{2n} L\right] \sin \frac{2\pi nt}{T}$

Again solving for Fourier coefficients for a specific value ℓ of n:

$$a_\ell \cos K_{2\ell} L + b_\ell \sin K_{2\ell} L = \frac{2}{T} \int_0^T T(o,L,t) \cos \frac{2\pi \ell t}{T} \, dt$$

$$a_\ell \sin K_{2\ell} - b_\ell \cos K_{2\ell} L = \frac{2}{T} \int_0^T T(o,L,t) \sin \frac{2\pi \ell t}{T} \, dt$$

Solve for $\sin K_{2\ell}$ and $\cos K_{2\ell}$ and thereby evaluate $K_{2\ell}$

Using $K_{1\ell}^2 + K_{2\ell}^2 = K_\ell^2$ solve for K_ℓ

Solve for $\theta_\ell = \cos^{-1} \frac{K_{1\ell}}{K_\ell}$

$= \sin^{-1} \frac{K_{2\ell}}{K_\ell}$

APPENDIX IV

THERMAL ARRAY DATA

The following is a listing of temperature data taken as part of the thermal array described previously. The data points have been tabulated from the wire resistance thermometer placed at the 700' depth at Apex buoy A and the two dan buoys D and E (Figure 2). The data were collected at one minute intervals for 17 1/2 hours on 12 March 1960, and are reported in degrees Centigrade.

APPENDIX VI

RADIATION DATA

The following is a listing of incident and reflected radiation data. The points were picked off the Brown recorder chart paper, averaged over 1/2 hourly intervals and tabulated.

REFLECTED RADIATION DATA

U. S. Navy Hydrographic Office
TONGUE OF THE OCEAN RESEARCH EXPERIMENT, by A. Wayne Magnitzky and Howard V. French, 1960. 132 p., 23 figs., 6 app. ASWEPS Report No. 3 (H. O. TR-94)

Bibliography

Oceanographic Cruise was made aboard USS SAN PABLO from 4 to 20 March 1960. A short discussion of the data is given together with illustrations. Data are tabulated and included as Appendixes I through VI. Analysis of data has not been completed.

1. Oceanography - Tongue of the Ocean
2. Tongue of the Ocean - Oceanography
3. ASWEPS

i. title: Tongue of the Ocean Research Experiment

ii. authors: A. Wayne Magnitzky and Howard V. French

iii. H. O. TR-94
